## INHIBITORS OF HISTONE DEACETYLASE

### BACKGROUND OF THE INVENTION

#### 10 Field of the Invention

This invention relates to the inhibition of histone deacetylase. More particularly, the invention relates to compounds and methods for inhibiting histone deacetylase enzymatic activity.

#### Summary of the Related Art

15 In eukaryotic cells, nuclear DNA associates with histones to form a compact complex called chromatin. The histones constitute a family of basic proteins which are generally highly conserved across eukaryotic species. The core histones, termed H2A, H2B, H3, and H4, associate to form a protein core. DNA winds around this protein core, with the basic amino acids of the histones 20 interacting with the negatively charged phosphate groups of the DNA. Approximately 146 base pairs of DNA wrap around a histone core to make up a nucleosome particle, the repeating structural motif of chromatin.

25 Csordas, *Biochem. J.*, 286: 23-38 (1990) teaches that histones are subject to posttranslational acetylation of the  $\epsilon$ -amino groups of N-terminal lysine residues, a reaction that is catalyzed by histone acetyl transferase (HAT1). Acetylation neutralizes the positive charge of the lysine side chain, and is thought to impact chromatin structure. Indeed, Taunton *et al.*, *Science*, 272: 408-411 (1996), teaches that access of transcription factors to chromatin templates is enhanced by histone hyperacetylation. Taunton *et al.* further teaches that an 30 enrichment in underacetylated histone H4 has been found in transcriptionally silent regions of the genome.

Histone acetylation is a reversible modification, with deacetylation being catalyzed by a family of enzymes termed histone deacetylases (HDACs). Grozinger *et al.*, *Proc. Natl. Acad. Sci. USA*, 96: 4868-4873 (1999), teaches that

5 HDACs may be divided into two classes, the first represented by yeast Rpd3-like proteins, and the second represented by yeast Hda1-like proteins. Grozinger *et al.* also teaches that the human HDAC1, HDAC2, and HDAC3 proteins are members of the first class of HDACs, and discloses new proteins, named HDAC4, HDAC5, and HDAC6, which are members of the second class of 10 HDACs. Kao *et al.*, *Genes & Dev.*, 14: 55-66 (2000), discloses HDAC7, a new member of the second class of HDACs. Van den Wyngaert, *FEBS*, 478: 77-83 (2000) discloses HDAC8, a new member of the first class of HDACs.

Richon *et al.*, *Proc. Natl. Acad. Sci. USA*, 95: 3003-3007 (1998), discloses that HDAC activity is inhibited by trichostatin A (TSA), a natural product isolated 15 from *Streptomyces hygroscopicus*, and by a synthetic compound, suberoylanilide hydroxamic acid (SAHA). Yoshida and Beppu, *Exper. Cell Res.*, 177: 122-131 (1988), teaches that TSA causes arrest of rat fibroblasts at the G<sub>1</sub> and G<sub>2</sub> phases of the cell cycle, implicating HDAC in cell cycle regulation. Indeed, Finnin *et al.*, *Nature*, 401: 188-193 (1999), teaches that TSA and SAHA inhibit cell growth, 20 induce terminal differentiation, and prevent the formation of tumors in mice.

These findings suggest that inhibition of HDAC activity represents a novel approach for intervening in cell cycle regulation and that HDAC inhibitors have great therapeutic potential in the treatment of cell proliferative diseases or 25 conditions. To date, only a few inhibitors of histone deacetylase are known in the art. There is thus a need to identify additional HDAC inhibitors and to identify the structural features required for potent HDAC inhibitory activity.

10 For purposes of the present invention, the following definitions will be used:

As used herein, the terms "histone deacetylase" and "HDAC" are intended to refer to any one of a family of enzymes that remove acetyl groups from the  $\epsilon$ -amino groups of lysine residues at the N-terminus of a histone. Unless otherwise indicated by context, the term "histone" is meant to refer to any 15 histone protein, including H1, H2A, H2B, H3, H4, and H5, from any species. Preferred histone deacetylases include class I and class II enzymes. Preferably the histone deacetylase is a human HDAC, including, but not limited to, HDAC-1, HDAC-2, HDAC-3, HDAC-4, HDAC-5, HDAC-6, HDAC-7, and HDAC-8. In other preferred embodiments, histone deacetylase activity is reduced by at least 95% and more preferably by at least 30 99%.

Preferably, such inhibition is specific, *i.e.*, the histone deacetylase inhibitor reduces the ability of a histone deacetylase to remove an acetyl group from a histone at a concentration that is lower than the concentration of the inhibitor that is required to produce another, unrelated biological effect. Preferably, the

5 concentration of the inhibitor required for histone deacetylase inhibitory activity is at least 2-fold lower, more preferably at least 5-fold lower, even more preferably at least 10-fold lower, and most preferably at least 20-fold lower than the concentration required to produce an unrelated biological effect.

### Synthesis

Compounds of formula Cy-L<sup>1</sup>-Ar-Y<sup>1</sup>-C(O)-NH-O-M, wherein L<sup>1</sup> is -S(O)<sub>2</sub>NH-, preferably may be prepared according to the synthetic routes depicted in Schemes 1-3. Accordingly, in certain preferred embodiments,

30       compounds I are preferably prepared according to the general synthetic route depicted in Scheme 1. Thus, a sulfonyl chloride (II) is treated with an amine (III) in a solvent such as methylene chloride in the presence of an organic base such as triethylamine. Treatment of the crude product with a base such as sodium methoxide in an alcoholic solvent such as methanol effects cleavage of any

5 dialkylated material and affords the sulfonamide (IV). Hydrolysis of the ester function in IV can be effected by treatment with a hydroxide base, such as lithium hydroxide, in a solvent mixture such as tetrahydrofuran and methanol to afford the corresponding acid (V).

**Scheme 1**

10

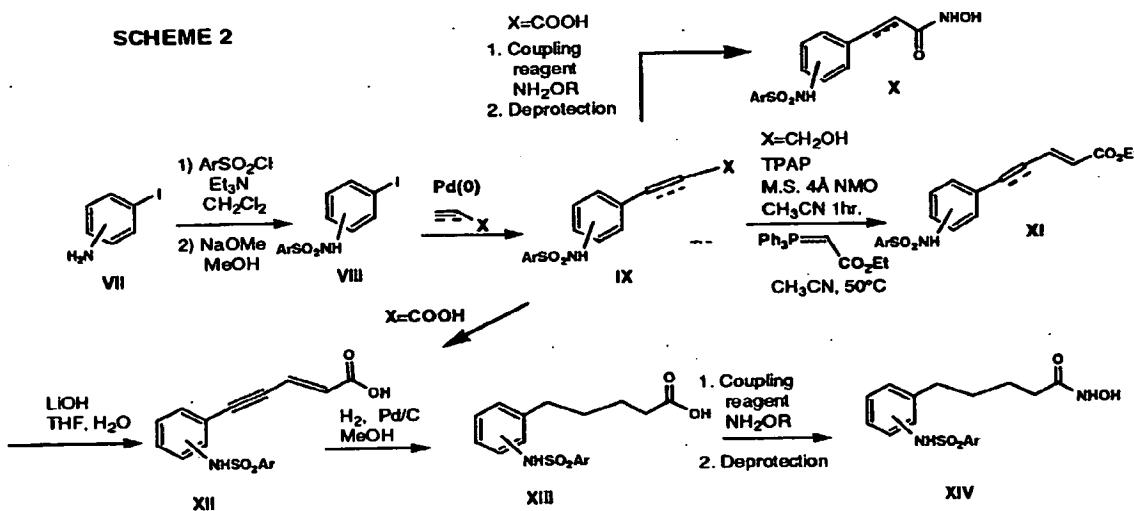

In some embodiments, conversion of the acid V to the hydroxamic acid I may be accomplished by coupling V with a protected hydroxylamine, such as tetrahydropyranylhydroxylamine ( $\text{NH}_2\text{OTHP}$ ), to afford the protected hydroxamate VI, followed by acidic hydrolysis of VI to provide the hydroxamic acid I. The coupling reaction is preferably accomplished with the coupling reagent dicyclohexylcarbodiimide (DCC) in a solvent such as methylene chloride (Method A) or with the coupling reagent 1-(3-dimethylaminopropyl)-3-ethylcarbodiimide in presence of *N*-hydroxy benzotriazole in an aprotic solvent

5 such as dimethylformamide (Method D). Other coupling reagents are known in the art and may also be used for this reaction. Hydrolysis of VI is preferably effected by treatment with an organic acid such as camphorsulfonic acid in a protic solvent such as methanol.

10 Alternatively, in some other embodiments, acid V is converted to the corresponding acid chloride, preferably by treatment with oxalic chloride, followed by the addition of a protected hydroxylamine such as O-trimethylsilylhydroxylamine in a solvent such as methylene chloride, which then provides the hydroxylamine I upon workup (Method C).

15 In still other embodiments, the ester IV is preferably treated with hydroxylamine in a solvent such as methanol in the presence of a base such as sodium methoxide to furnish the hydroxylamine I directly (Method B).

SCHEME 2

20 Compounds of formula X and XIV preferably are prepared according to the general procedure outlined in Scheme 2. Thus, an aminoaryl halide (VII) is treated with a sulfonyl chloride in presence of a base such as triethylamine, followed by treatment with an alkoxide base, to furnish the sulfonamide VIII. One of skill in the art will recognize that reverse sulfonamide analogs can be readily prepared by an analogous procedure, treating a haloarenesulfonyl halide with an arylamine.

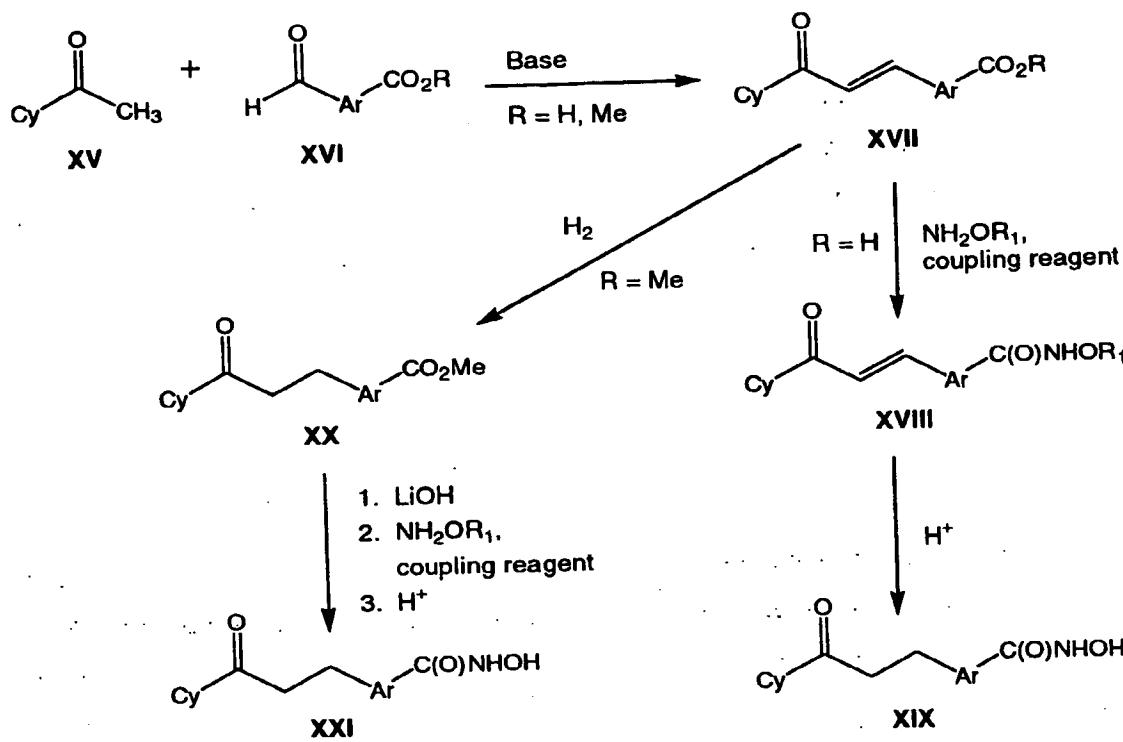

5        Compound **VIII** is coupled with a terminal acetylene or olefinic compound in the presence of a palladium catalyst such as tetrakis(triphenylphosphine)palladium(0) in a solvent such as pyrrolidine to afford **IX**.

10      Oxidation of the compound of formula **IX** ( $X=CH_2OH$ ), followed by homologation of the resulting aldehyde using a Wittig type reagent such as carbethoxymethylenetriphenylphosphorane in a solvent such as acetonitrile, gives the compound of formula **XI**. Basic hydrolysis of **XI**, such as by treatment with lithium hydroxide in a mixture of THF and water, provides the acid **XII**. Hydrogenation of **XII** may preferably be performed over a palladium catalyst such as Pd/C in a protic solvent such as methanol to afford the saturated acid **XIII**. Coupling of the acid **XIII** with an O-protected hydroxylamine such as O-tetrahydropyranylhydroxylamine is effected by treatment with a coupling reagent such as 1-(3-dimethylaminopropyl)-3-ethylcarbodiimide in the presence of N-hydroxybenzotriazole (HOBT), or N,N-dicyclohexylcarbodiimide (DCC), in a solvent such as DMF, followed by deprotection to furnish the compound of general formula **XIV**.

15      The acid **IX**, wherein  $X=COOH$ , may be coupled directly with an O-protected hydroxylamine such as O-tetrahydropyranylhydroxylamine, followed by deprotection of the hydroxy protecting group to furnish the hydroxamic acid **X**.

20      Compounds of formula  $Cy-L'-Ar-Y'-C(O)-NH-O-M$ , wherein  $L'$  is  $-C(O)NH-$ , preferably may be prepared according to the synthetic routes analogous to those depicted in Schemes 1-2, substituting acid chloride starting materials for the sulfonyl chloride starting materials in those Schemes.

Scheme 3

5

Compounds of the formula Cy-L<sup>2</sup>-Ar-Y<sup>2</sup>-C(O)-NH-O-M are preferably prepared according to the synthetic routes outlined in Schemes 3-5.

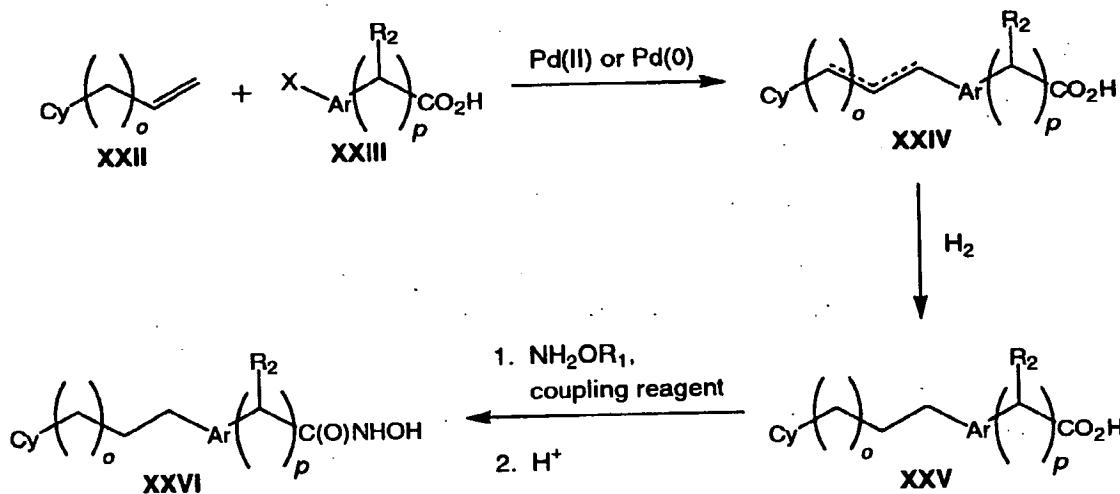

Accordingly, in certain preferred embodiments, compounds of formulae XIX and XXI (L<sup>2</sup> = -C(O)-CH=CH- or -C(O)-CH<sub>2</sub>CH<sub>2</sub>-) preferably are prepared according to the route described in Scheme 3. Thus, a substituted aryl acetophenone (XV) is treated with an aryl aldehyde (XVI) in a protic solvent such as methanol in the presence of a base such as sodium methoxide to afford the enone XVII.

The acid substituent of XVII (R = H) is coupled with an O-protected hydroxylamine such as O-tetrahydropyranylhydroxylamine (R<sub>1</sub> = tetrahydropyran-2-yl) to afford the O-protected-N-hydroxybenzamide XVIII. The coupling reaction is preferably performed by treating the acid and

5 hydroxylamine with dicyclohexylcarbodiimide in a solvent such as methylene chloride or with 1-(3-dimethylaminopropyl)-3-ethylcarbodiimide in the presence of *N*-hydroxybenzotriazole in a solvent such as dimethylformamide. Other coupling reagents are known in the art and may also be used in this reaction. O-Deprotection is accomplished by treatment of XVIII with an acid such as 10 camphorsulfonic acid in a solvent such as methanol to afford the hydroxamic acid XIX ( $L^2 = -C(O)-CH=CH-$ ).

Saturated compounds of formula XXI ( $L^2 = -C(O)-CH_2CH_2-$ ) are preferably prepared by hydrogenation of XVII ( $R = Me$ ) over a palladium catalyst, such as 10% Pd/C, in a solvent such as methanol-tetrahydrofuran. 15 Basic hydrolysis of the resultant product XIX with lithium hydroxide, followed by *N*-hydroxy amide formation and acid hydrolysis as described above, then affords the hydroxamic acid XXI.

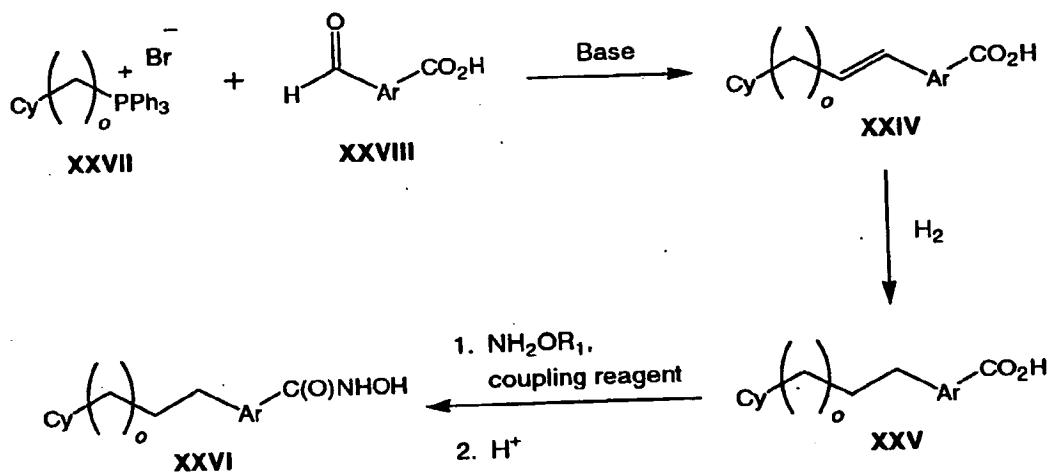

**Scheme 4**

20

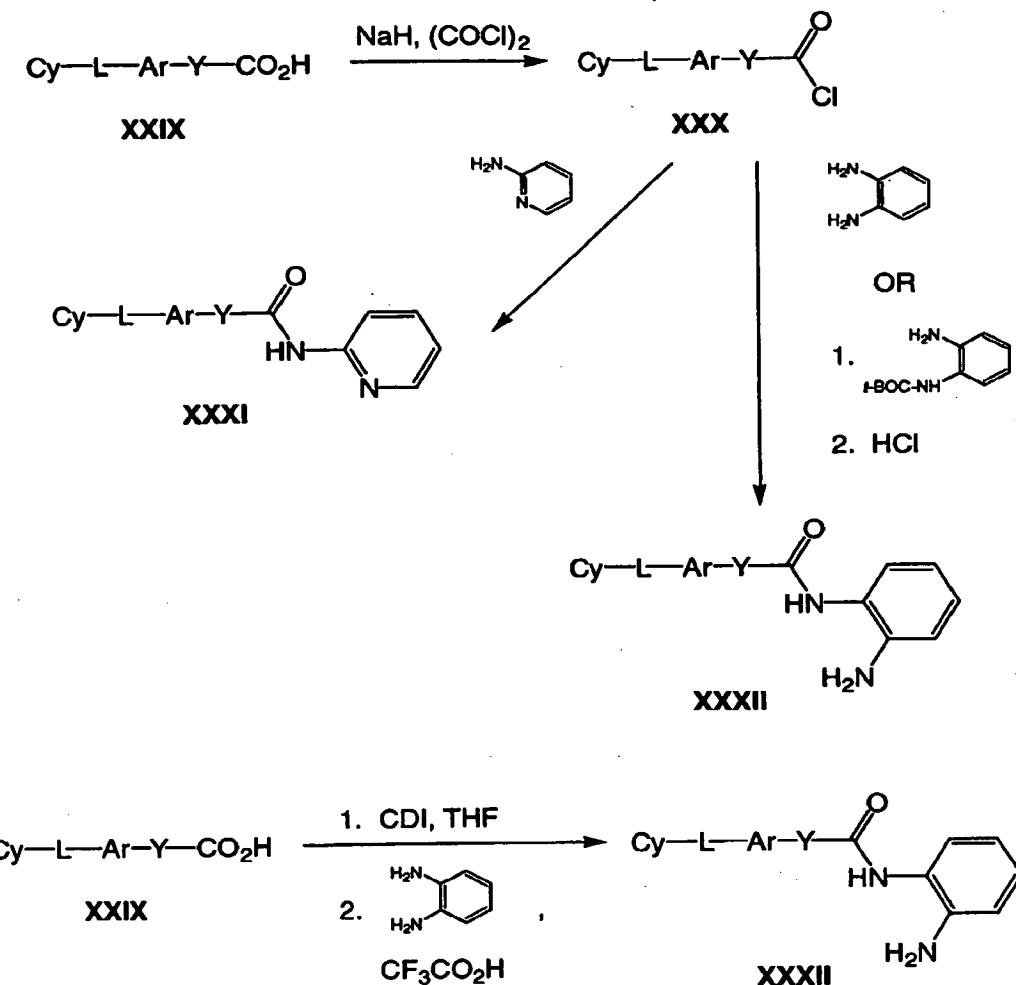

Compounds of formula XXVI ( $L^2 = -(CH_2)_{m-1}-$ ) are preferably prepared by the general procedures described in Schemes 4 and 5. Thus, in some

5 embodiments, a terminal olefin (XXII) is coupled with an aryl halide (XXIII) in the presence of a catalytic amount of a palladium source, such as palladium acetate or tris(dibenzylideneacetone)dipalladium(0), a phosphine, such as triphenylphosphine, and a base, such as triethylamine, in a solvent such as acetonitrile to afford the coupled product XXIV. Hydrogenation, followed by 10 *N*-hydroxyamide formation and acid hydrolysis, as described above, affords the hydroxamic acid XXVI.

**Scheme 5**

15 Alternatively, in some other embodiments, a phosphonium salt of formula XXVII is treated with an aryl aldehyde of formula XXVIII in the presence of base, such as lithium hexamethyldisilazide, in a solvent, such as tetrahydrofuran, to produce the compound XXIV. Hydrogenation, followed by 20 *N*-hydroxyamide formation and acidic hydrolysis, then affords the compounds XXVI.

Scheme 6

5

An acid of formula Cy-L-Ar-Y-C(O)-OH (XXIX), prepared by one of the methods shown in Schemes 1-5, is converted to the corresponding acid chloride XXX according to standard methods, e.g., by treatment with sodium hydride and oxalyl chloride. Treatment of XXX with 2-aminopyridine and a tertiary base such as N-methylmorpholine, preferably in dichloromethane at reduced temperature, then affords the pyridyl amide XXXI.

10

5 In a similar fashion, the acid chloride XXX may be treated with 1,2-phenylenediamine to afford the anilinyl amide XXXII. Alternatively, the acid chloride XXX may be treated with a mono-protected 1,2-phenylenediamine, such as 2-(*t*-BOC-amino)aniline, followed by deprotection, to afford XXXII.

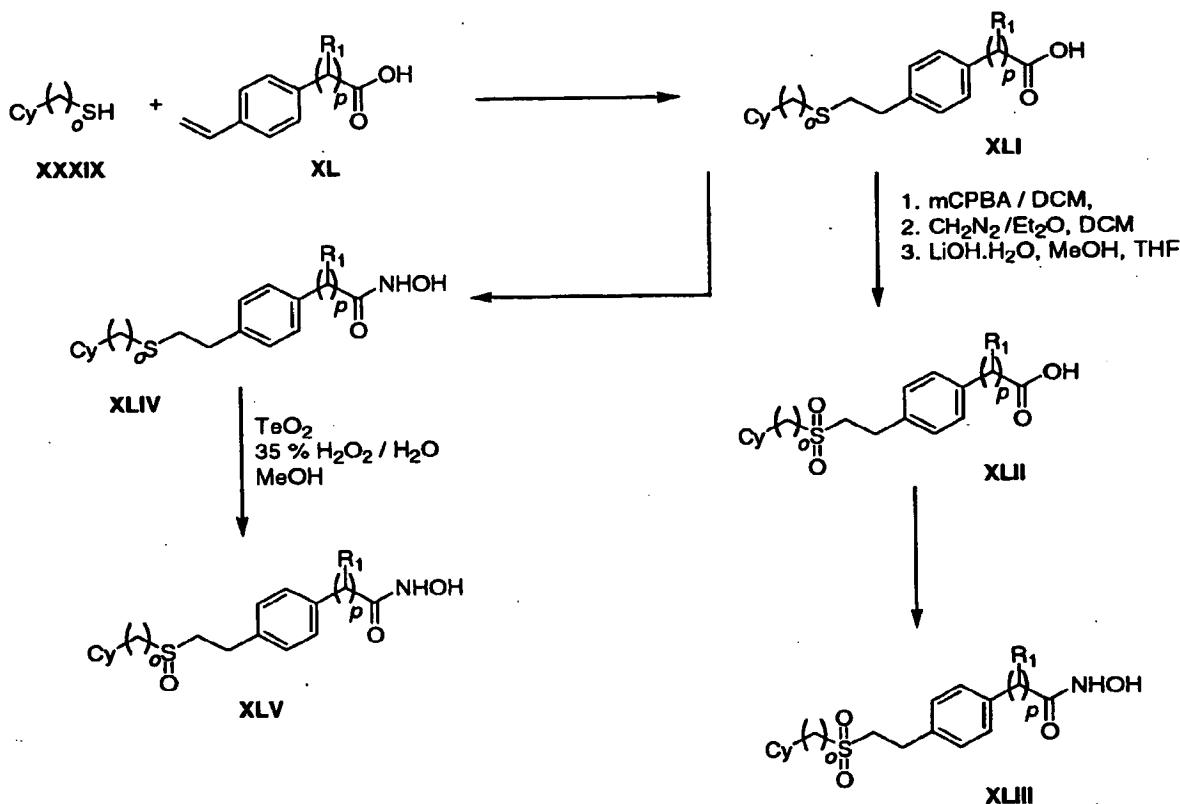

10 In another alternative procedure, the acid XXIX may be activated by treatment with carbonyldiimidazole (CDI), followed by treatment with 1,2-phenylenediamine and trifluoroacetic acid to afford the anilinyl amide XXXII.

**Scheme 7**

15 Compounds of formula XXXVIII ( $\text{L}^2 = -\text{C}(\text{O})\text{-alkylene-}$ ) preferably are prepared according to the general procedure depicted in Scheme 7. Thus, Aldol condensation of ketone XXXIII ( $\text{R}_1 = \text{H}$  or alkyl) with aldehyde XXXIV affords the adduct XXXV. The adduct XXXV may be directly converted to the corresponding hydroxamic acid XXXVI, or may first undergo hydrogenation to

5 afford the saturated compound **XXVII** and then be converted to the hydroxamic acid **XXXVIII**.

**Scheme 8**

10

Compounds of formula (2), wherein one of the carbon atoms in  $\text{L}^2$  is replaced with S, S(O), or S(O)<sub>2</sub>, preferably are prepared according to the general procedure outlined in Scheme 8. Thus, thiol XXXIX is added to olefin XL to produce XLI. The reaction is preferably conducted in the presence of a radical initiator such as 2,2'-azobisisobutyronitrile (AIBN) or 1,1'-azobis(cyclohexanecarbonitrile) (VAZO<sup>TM</sup>). Sulfide oxidation, preferably by treatment with *m*-chloroperbenzoic acid (mCPBA), affords the corresponding sulfone, which is conveniently isolated after conversion to the methyl ester by

15

5 treatment with diazomethane. Ester hydrolysis then affords the acid XLII, which is converted to the hydroxamic acid XLIII according to any of the procedures described above. The sulfide XLI also may be converted directly to the corresponding hydroxamic acid XLIV, which then may be selectively oxidized to the sulfoxide XLV, for example, by treatment with hydrogen  
10 peroxide and tellurium dioxide.

### Pharmaceutical Compositions

In a second aspect, the invention provides pharmaceutical compositions comprising an inhibitor of histone deacetylase represented by any one of  
15 formulae (1)-(6) and a pharmaceutically acceptable carrier, excipient, or diluent. Compounds of the invention may be formulated by any method well known in the art and may be prepared for administration by any route, including, without limitation, parenteral, oral, sublingual, transdermal, topical, intranasal, intratracheal, or intrarectal. In certain preferred embodiments, compounds of  
20 the invention are administered intravenously in a hospital setting. In certain other preferred embodiments, administration may preferably be by the oral route.

The characteristics of the carrier will depend on the route of administration. As used herein, the term "pharmaceutically acceptable" means a

Thus, compositions according to the invention may contain, in addition to the inhibitor, diluents, fillers, salts, buffers, stabilizers, solubilizers, and other materials well known in the art. The  
30 preparation of pharmaceutically acceptable formulations is described in, e.g., *Remington's Pharmaceutical Sciences*, 18th Edition, ed. A. Gennaro, Mack Publishing Co., Easton, PA, 1990.

## 5 Inhibition of Histone Deacetylase

In a third aspect, the invention provides a method of inhibiting histone deacetylase in a cell, comprising contacting a cell in which inhibition of histone deacetylase is desired with an inhibitor of histone deacetylase according to the invention. In a first embodiment according to this aspect of the invention, the 10 inhibitor of histone deacetylase is represented by the formula (1)

wherein

Cy is cycloalkyl, aryl, heteroaryl, or heterocyclyl, any of which may be optionally substituted;

15 L' is  $-(\text{CH}_2)_m-\text{W}-$ , where m is 0, 1, 2, 3, or 4, and W is selected from the group consisting of  $-\text{C}(\text{O})\text{NH}-$ ,  $-\text{S}(\text{O})_2\text{NH}-$ ,  $-\text{NHC}(\text{O})-$ ,  $-\text{NHS}(\text{O})_2-$ , and  $-\text{NH}-\text{C}(\text{O})-\text{NH}-$ ;

20 Ar is arylene, wherein said arylene optionally may be additionally substituted and optionally may be fused to an aryl or heteroaryl ring, or to a saturated or partially unsaturated cycloalkyl or heterocyclic ring, any of which may be optionally substituted;

Y' is a chemical bond or a straight- or branched-chain saturated alkylene, wherein said alkylene may be optionally substituted; and

25 Z is selected from the group consisting of anilinyl, pyridyl, 2-thioxo-1,3,4-thiadiazol-2-yl, and  $-\text{O}-\text{M}$ , M being H or a pharmaceutically acceptable cation; provided that when L' is  $-\text{C}(\text{O})\text{NH}-$ , Y is  $-(\text{CH}_2)_n-$ , n being 1, 2, or 3, and Z is  $-\text{O}-\text{M}$ , then Cy is not aminophenyl, dimethylaminophenyl, or hydroxyphenyl.

In a second embodiment according to this aspect of the invention, the 30 inhibitor of histone deacetylase is represented by formula (2):

25 Z is selected from the group consisting of anilinyl, pyridyl, 2-thioxo-1,3,4-thiadiazol-2-yl, and -O-M, M being H or a pharmaceutically acceptable cation.

30 In a third embodiment according to this aspect of the invention, the inhibitor of histone deacetylase is represented by the formula (3):

$$\text{Cy-L'-Ar-Y'-C(O)NH-Z} \quad (3)$$

wherein

35 Cy is cycloalkyl, aryl, heteroaryl, or heterocyclyl, any of which may be optionally substituted, provided that Cy is not a (spirocycloalkyl)heterocyclyl;

40 L' is selected from the group consisting of

45 (a) -(CH<sub>2</sub>)<sub>m</sub>-W-, where m is 0, 1, 2, 3, or 4, and W is selected from the group consisting of -C(O)NH-, -S(O)<sub>2</sub>NH-, -NHC(O)-, -NHS(O)<sub>2</sub>-, and -NH-C(O)-NH-; and

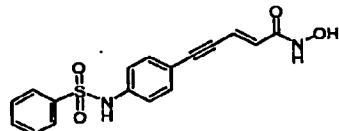

50 (b) C<sub>1</sub>-C<sub>6</sub> alkylene or C<sub>2</sub>-C<sub>6</sub> alkenylene, wherein the alkylene or alkenylene optionally may be substituted, provided that L' is not -C(O)-, and wherein one of the carbon atoms of the alkylene optionally may be replaced by O; NR', R' being alkyl, acyl, or hydrogen; S; S(O); or S(O)<sub>2</sub>;

5 Ar is arylene, wherein said arylene optionally may be additionally substituted and optionally may be fused to an aryl or heteroaryl ring, or to a saturated or partially unsaturated cycloalkyl or heterocyclic ring, any of which may be optionally substituted; and

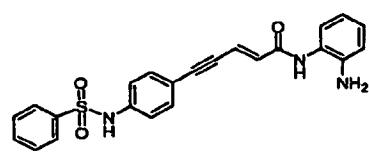

10 Y<sup>3</sup> is C<sub>2</sub> alkenylene or C<sub>2</sub> alkynylene, wherein one or both carbon atoms of the alkenylene optionally may be substituted with alkyl, aryl, alkaryl, or aralkyl; and

Z is selected from the group consisting of anilinyl, pyridyl, thiadiazolyl, and -O-M, M being H or a pharmaceutically acceptable cation; provided that when Cy is unsubstituted phenyl, Ar is not phenyl wherein  
15 L<sup>3</sup> and Y<sup>3</sup> are oriented *ortho* or *meta* to each other.

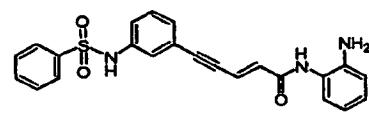

In a fourth embodiment according to this aspect of the invention, the novel histone deacetylase inhibitor is selected from the group represented by formulae (4)-(6):

(4)

(5)

(6)

Measurement of the enzymatic activity of a histone deacetylase can be  
25 achieved using known methodologies. For example, Yoshida *et al.*, *J. Biol. Chem.*, 265: 17174-17179 (1990), describes the assessment of histone deacetylase

5 enzymatic activity by the detection of acetylated histones in trichostatin A treated cells. Taunton *et al.*, *Science*, 272: 408-411 (1996), similarly describes methods to measure histone deacetylase enzymatic activity using endogenous and recombinant HDAC-1. Both of these references are hereby incorporated by reference in their entirety.

10 In some preferred embodiments, the histone deacetylase inhibitor interacts with and reduces the activity of all histone deacetylases in the cell. In some other preferred embodiments according to this aspect of the invention, the histone deacetylase inhibitor interacts with and reduces the activity of fewer than all histone deacetylases in the cell. In certain preferred embodiments, the 15 inhibitor interacts with and reduces the activity of one histone deacetylase (e.g., HDAC-1), but does not interact with or reduce the activities of other histone deacetylases (e.g., HDAC-2, HDAC-3, HDAC-4, HDAC-5, HDAC-6, HDAC-7, and HDAC-8). As discussed below, certain particularly preferred histone deacetylase inhibitors are those that interact with and reduce the enzymatic 20 activity of a histone deacetylase that is involved in tumorigenesis. Certain other preferred histone deacetylase inhibitors interact with and reduce the enzymatic activity of a fungal histone deacetylase.

Preferably, the method according to the third aspect of the invention causes an inhibition of cell proliferation of the contacted cells. The phrase 25 "inhibiting cell proliferation" is used to denote an ability of an inhibitor of histone deacetylase to retard the growth of cells contacted with the inhibitor as compared to cells not contacted. An assessment of cell proliferation can be made by counting contacted and non-contacted cells using a Coulter Cell Counter (Coulter, Miami, FL) or a hemacytometer. Where the cells are in a solid growth 30 (e.g., a solid tumor or organ), such an assessment of cell proliferation can be made by measuring the growth with calipers and comparing the size of the growth of contacted cells with non-contacted cells.

Preferably, growth of cells contacted with the inhibitor is retarded by at least 50% as compared to growth of non-contacted cells. More preferably, cell

5 proliferation is inhibited by 100% (i.e., the contacted cells do not increase in number). Most preferably, the phrase "inhibiting cell proliferation" includes a reduction in the number or size of contacted cells, as compared to non-contacted cells. Thus, an inhibitor of histone deacetylase according to the invention that inhibits cell proliferation in a contacted cell may induce the contacted cell to

10 undergo growth retardation, to undergo growth arrest, to undergo programmed cell death (i.e., to apoptose), or to undergo necrotic cell death.

The cell proliferation inhibiting ability of the histone deacetylase inhibitors according to the invention allows the synchronization of a population of asynchronously growing cells. For example, the histone deacetylase

15 inhibitors of the invention may be used to arrest a population of non-neoplastic cells grown *in vitro* in the G1 or G2 phase of the cell cycle. Such synchronization allows, for example, the identification of gene and/or gene products expressed during the G1 or G2 phase of the cell cycle. Such a synchronization of cultured cells may also be useful for testing the efficacy of a new transfection protocol,

20 where transfection efficiency varies and is dependent upon the particular cell cycle phase of the cell to be transfected. Use of the histone deacetylase inhibitors of the invention allows the synchronization of a population of cells, thereby aiding detection of enhanced transfection efficiency.

In some preferred embodiments, the contacted cell is a neoplastic cell. The

25 term "neoplastic cell" is used to denote a cell that shows aberrant cell growth. Preferably, the aberrant cell growth of a neoplastic cell is increased cell growth. A neoplastic cell may be a hyperplastic cell, a cell that shows a lack of contact

inhibition of growth *in vitro*, a benign tumor cell that is incapable of metastasis *in vivo*, or a cancer cell that is capable of metastasis *in vivo* and that may recur after

30 attempted removal. The term "tumorigenesis" is used to denote the induction of cell proliferation that leads to the development of a neoplastic growth. In some embodiments, the histone deacetylase inhibitor induces cell differentiation in the contacted cell. Thus, a neoplastic cell, when contacted with an inhibitor of

5 histone deacetylase may be induced to differentiate, resulting in the production of a daughter cell that is phylogenetically more advanced than the contacted cell.

In some preferred embodiments, the contacted cell is in an animal. Thus, the invention provides a method for treating a cell proliferative disease or condition in an animal, comprising administering to an animal in need of such

10 treatment a therapeutically effective amount of a histone deacetylase inhibitor of the invention. Preferably, the animal is a mammal, more preferably a domesticated mammal. Most preferably, the animal is a human.

The term "cell proliferative disease or condition" is meant to refer to any condition characterized by aberrant cell growth, preferably abnormally

15 increased cellular proliferation. Examples of such cell proliferative diseases or conditions include, but are not limited to, cancer, restenosis, and psoriasis. In particularly preferred embodiments, the invention provides a method for inhibiting neoplastic cell proliferation in an animal comprising administering to an animal having at least one neoplastic cell present in its body a therapeutically 20 effective amount of a histone deacetylase inhibitor of the invention.

It is contemplated that some compounds of the invention have inhibitory activity against a histone deacetylase from a protozoal source. Thus, the invention also provides a method for treating or preventing a protozoal disease or infection, comprising administering to an animal in need of such treatment a 25 therapeutically effective amount of a histone deacetylase inhibitor of the invention. Preferably the animal is a mammal, more preferably a human.

Preferably, the histone deacetylase inhibitor used according to this embodiment of the invention inhibits a protozoal histone deacetylase to a greater extent than it inhibits mammalian histone deacetylases, particularly human histone

30 deacetylases.

The present invention further provides a method for treating a fungal disease or infection comprising administering to an animal in need of such treatment a therapeutically effective amount of a histone deacetylase inhibitor of the invention. Preferably the animal is a mammal, more preferably a human.

5 Preferably, the histone deacetylase inhibitor used according to this embodiment of the invention inhibits a fungal histone deacetylase to a greater extent than it inhibits mammalian histone deacetylases, particularly human histone deacetylases.

The term "therapeutically effective amount" is meant to denote a dosage sufficient to cause inhibition of histone deacetylase activity in the cells of the subject, or a dosage sufficient to inhibit cell proliferation or to induce cell differentiation in the subject. Administration may be by any route, including, without limitation, parenteral, oral, sublingual, transdermal, topical, intranasal, intratracheal, or intrarectal. In certain particularly preferred embodiments, compounds of the invention are administered intravenously in a hospital setting. In certain other preferred embodiments, administration may preferably be by the oral route.

When administered systemically, the histone deacetylase inhibitor is preferably administered at a sufficient dosage to attain a blood level of the inhibitor from about 0.01 M to about 100 M, more preferably from about 0.05 M to about 50 M, still more preferably from about 0.1 M to about 25 M, and still yet more preferably from about 0.5 M to about 25 M. For localized administration, much lower concentrations than this may be effective, and much higher concentrations may be tolerated. One of skill in the art will appreciate that the dosage of histone deacetylase inhibitor necessary to produce a therapeutic effect may vary considerably depending on the tissue, organ, or the particular animal or patient to be treated.

In certain preferred embodiments of the fifth and sixth aspects of the invention, the method further comprises contacting the cell with an antisense oligonucleotide that inhibits the expression of a histone deacetylase. The combined use of a nucleic acid level inhibitor (i.e., antisense oligonucleotide) and a protein level inhibitor (i.e., inhibitor of histone deacetylase enzyme activity) results in an improved inhibitory effect, thereby reducing the amounts of the inhibitors required to obtain a given inhibitory effect as compared to the

5 amounts necessary when either is used individually. The antisense oligonucleotides according to this aspect of the invention are complementary to regions of RNA or double-stranded DNA that encode HDAC-1, HDAC-2, HDAC-3, HDAC-4, HDAC-5, HDAC-6, HDAC7, and/or HDAC-8.

For purposes of the invention, the term "oligonucleotide" includes 10 polymers of two or more deoxyribonucleosides, ribonucleosides, or 2'-O-substituted ribonucleoside residues, or any combination thereof. Preferably, such oligonucleotides have from about 6 to about 100 nucleoside residues, more preferably from about 8 to about 50 nucleoside residues, and most preferably from about 12 to about 30 nucleoside residues. The nucleoside residues may be 15 coupled to each other by any of the numerous known internucleoside linkages. Such internucleoside linkages include without limitation phosphorothioate, phosphorodithioate, alkylphosphonate, alkylphosphonothioate, phosphotriester, phosphoramidate, siloxane, carbonate, carboxymethyleneester, acetamide, carbamate, thioether, bridged phosphoramidate, bridged methylene 20 phosphonate, bridged phosphorothioate and sulfone internucleoside linkages. In certain preferred embodiments, these internucleoside linkages may be phosphodiester, phosphotriester, phosphorothioate, or phosphoramidate linkages, or combinations thereof. The term oligonucleotide also encompasses such polymers having chemically modified bases or sugars and/ or having 25 additional substituents, including without limitation lipophilic groups, intercalating agents, diamines and adamantane. For purposes of the invention the term "2'-O-substituted" means substitution of the 2' position of the pentose moiety with an -O-lower alkyl group containing 1-6 saturated or unsaturated carbon atoms, or with an -O-aryl or allyl group having 2-6 carbon atoms, 30 wherein such alkyl, aryl or allyl group may be unsubstituted or may be substituted, e.g., with halo, hydroxy, trifluoromethyl, cyano, nitro, acyl, acyloxy, alkoxy, carboxyl, carbalkoxyl, or amino groups; or such 2' substitution may be with a hydroxy group (to produce a ribonucleoside), an amino or a halo group,

5 but not with a 2'-H group. The term "oligonucleotide" also encompasses linked nucleic acid and peptide nucleic acid.

Particularly preferred antisense oligonucleotides utilized in this aspect of the invention include chimeric oligonucleotides and hybrid oligonucleotides.

For purposes of the invention, a "chimeric oligonucleotide" refers to an 10 oligonucleotide having more than one type of internucleoside linkage. One preferred example of such a chimeric oligonucleotide is a chimeric oligonucleotide comprising a phosphorothioate, phosphodiester or phosphorodithioate region, preferably comprising from about 2 to about 12 nucleotides, and an alkylphosphonate or alkylphosphonothioate region (see e.g., 15 Pederson *et al.* U.S. Patent Nos. 5,635,377 and 5,366,878). Preferably, such chimeric oligonucleotides contain at least three consecutive internucleoside linkages selected from phosphodiester and phosphorothioate linkages, or combinations thereof.

For purposes of the invention, a "hybrid oligonucleotide" refers to an 20 oligonucleotide having more than one type of nucleoside. One preferred example of such a hybrid oligonucleotide comprises a ribonucleotide or 2'-O-substituted ribonucleotide region, preferably comprising from about 2 to about 12 2'-O-substituted nucleotides, and a deoxyribonucleotide region. Preferably, such a hybrid oligonucleotide will contain at least three consecutive 25 deoxyribonucleosides and will also contain ribonucleosides, 2'-O-substituted ribonucleosides, or combinations thereof (see e.g., Metelev and Agrawal, U.S. Patent No. 5,652,355).

The exact nucleotide sequence and chemical structure of an antisense oligonucleotide utilized in the invention can be varied, so long as the 30 oligonucleotide retains its ability to inhibit expression of the gene of interest. This is readily determined by testing whether the particular antisense oligonucleotide is active by quantitating the mRNA encoding a product of the gene, or in a Western blotting analysis assay for the product of the gene, or in an activity assay for an enzymatically active gene product, or in a soft agar growth

5 assay, or in a reporter gene construct assay, or an *in vivo* tumor growth assay, all of which are described in detail in this specification or in Ramchandani *et al.* (1997) Proc. Natl. Acad. Sci. USA 94: 684-689.

Antisense oligonucleotides utilized in the invention may conveniently be synthesized on a suitable solid support using well known chemical approaches, 10 including H-phosphonate chemistry, phosphoramidite chemistry, or a combination of H-phosphonate chemistry and phosphoramidite chemistry (*i.e.*, H-phosphonate chemistry for some cycles and phosphoramidite chemistry for other cycles). Suitable solid supports include any of the standard solid supports used for solid phase oligonucleotide synthesis, such as controlled-pore glass 15 (CPG) (see, *e.g.*, Pon, R.T. (1993) Methods in Molec. Biol. 20: 465-496).

Particularly, preferred oligonucleotides have nucleotide sequences of from about 13 to about 35 nucleotides which include the nucleotide sequences shown in Tables 1-3. Yet additional particularly preferred oligonucleotides have nucleotide sequences of from about 15 to about 26 nucleotides of the nucleotide 20 sequences shown in Tables 1-3.

The mixture was stirred 4 h then a white precipitate was formed. A saturated aqueous solution of  $\text{NaHCO}_3$  was added and the phases were separated. The aqueous layer was extracted several times with  $\text{CH}_2\text{Cl}_2$  and the combined extracts were dried over ( $\text{MgSO}_4$ ) then evaporated. 5 dichloromethane (0.1 M) at 0° C was added portionwise 3-chloroperbenzoic acid (Aldrich Chemical Co., 57-86 % pure solid by, 2 g, 6.97 mmoles), as described by Nicolaou *et al.*, *J. Am. Chem. Dimethyl sulfide (5 mL) was added, the mixture was diluted in dichloromethane and washed 3 times with

5 Example 30Step 1: Ethyl 3-(4-nitrophenyl)-2-isopropyl propanoate (78)

To a precooled solution of diisopropylamine (34.7 mmol) in THF (30 mL) under nitrogen was added dropwise a 1.0 M solution of *n*-butyllithium (33.3 mmol). The resulting light yellow solution was stirred at -78°C over 30 minutes and transferred via canula to a precooled (-78°C) solution of ethyl isovalerate (34.7 mmol) in THF (50 mL). The mixture was stirred at -78°C over 1 hour and a 4-nitrobenzyl bromide (13.9 mmol) solution in THF (20 mL) at room temperature was transferred dropwise via canula to the enolate solution which turned deep red. The mixture was stirred over 15 minutes and the reaction was quenched with aqueous saturated ammonium chloride solution (NH<sub>4</sub>Cl). The mixture was allowed to warm to room temperature over 1 hour and turned brown upon warming. It was poured into a large volume of saturated NH<sub>4</sub>Cl solution and

5 the layers were separated. The aqueous layer was extracted twice with diethyl ether and the combined organic layers were washed with brine, dried over magnesium sulfate and concentrated *in vacuo*. The residue was purified by flash chromatography on silica gel using ethyl acetate and hexanes (10:90) as the eluent, yielding 73% of the pure title compound 78 as a light yellow oil.

10 **Step 2: Ethyl 3-(4-aminophenyl)2-isopropyl propanoate (79):**

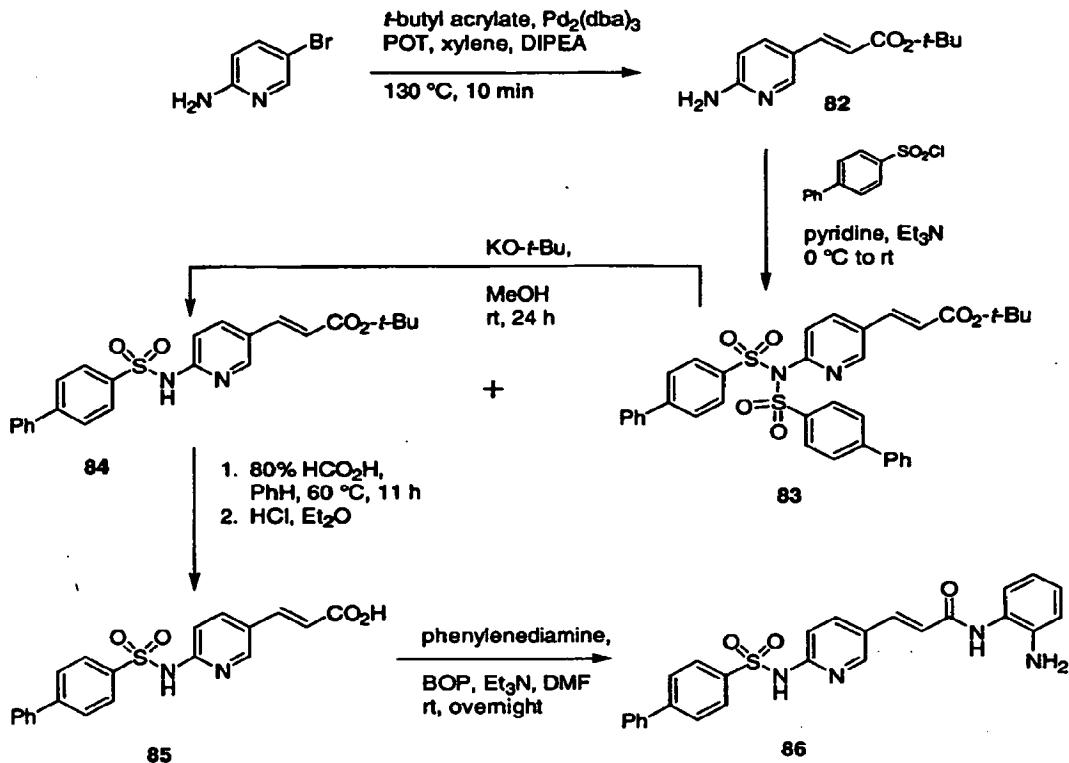

To a hydrogen flushed (vacuum/H<sub>2</sub>, 3 times) solution of 1 (1.88 mmol) in methanol (10 mL) was added 10% palladium on charcoal (0.018 mmol) previously quenched with methanol in a separate flask. The black heterogeneous resulting mixture was stirred at room temperature under 15 hydrogen atmosphere (1 atm) over 20 hours. The hydrogen was then evacuated by vacuum and replaced with air. Then, the mixture was filtered through celite, rinsing with methanol while making sure the pad never gets dry. The filtrate was concentrated to a red oil. The residue was purified by flash chromatography on silica gel using ethyl acetate and hexanes (30:70) as the eluent, yielding 73% of 20 the pure title compound 79 as a light red oil.

**Steps 3-5: (81)**

Compound 79 was coupled with benzenesulfonyl chloride in the presence of triethylamine according to the procedure described in Example 1, step 1, to afford the sulfonamide 80. Ester hydrolysis and coupling with hydroxylamine 25 were then accomplished as described in Example 28 to afford the hydroxamic acid 81.

5 Example 31:

Compound 82 was obtained in good yield from commercially available bromoaminopyridine through a palladium catalyzed coupling with tert-butyl acrylate. Treatment of 82 with 4-phenylbenzenesulfonyl chloride afforded a mixture of sulfonamide 84 and bis-sulfonamide 83, which was converted to 84 upon chromatographic isolation followed by basic methanolysis. Acidic cleavage of the *t*-butyl ester was effected by treatment of 84 with aqueous formic acid and a *t*-butyl cation scavenger to afford the acrylic acid 85 in quantitative yield. Finally, coupling of 85 with *o*-phenylenediamine in the presence of benzotriazol-1-yloxytris(dimethylamino)phosphonium hexafluorophosphate (BOP) afforded the anilide 86.

5 Example 32:

Sulfonamide 124 was prepared by condensation of 4-iodoaniline with 10 benzenesulfonyl chloride. Compound 125 was quantitatively furnished by a Pd-Cu catalyzed coupling reaction of 124 with propargyl alcohol in basic solvent. Primary alcohol 125 was oxidized to the corresponding carboxylic acid 127 in two steps, including Dess-Martin periodinane oxidation to afford aldehyde 126, followed by treatment with sodium chlorite in buffered aqueous media in the presence of a chlorine scavenger. Acid 127 was derivatized to the hydroxamic acid 128 by treatment with hydroxylamine hydrochloride and the coupling reagent EDC in the presence of N-hydroxybenzotriazole in basic, aprotic media.

15

5 Compound 129 was prepared by coupling acid 130 with *o*-phenylenediamine as described in Example 31 for compound 86.

5 Example 33:

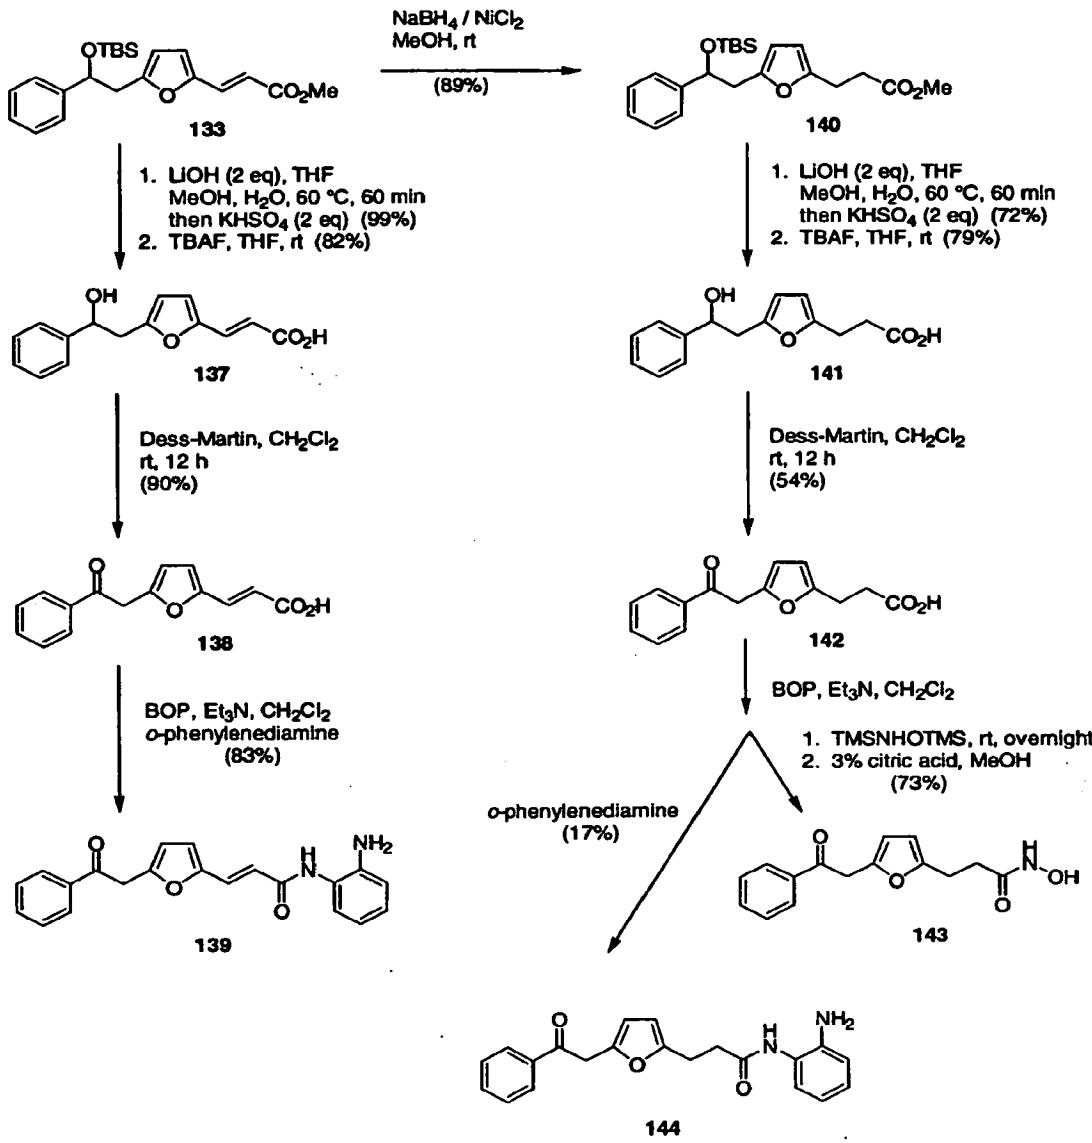

Benzyllic alcohol 130 was prepared in 53 % yield by addition of 2-lithiofuran to styrene oxide. After protection of the resulting hydroxyl group 10 with *tert*-butyldimethylsilyl chloride, the lithiated species of compound 131 was treated with DMF to afford the formyl derivative 132. Wadsworth-Horner-Emmons olefination was effected by treatment of 132 with the sodium enolate of trimethylphosphonoacetate to afford the key intermediate 133 in 90 % overall yield for the last three steps. Saponification of the methyl ester with LiOH 15 yielded the acid 134, which in turn was converted into its hydroxamic acid form

5 **135** by conventional activation with HOBr / EDC, followed by reaction with hydroxylamine. Fluoride-promoted cleavage of silylated ether gave alcohol **136** in 67 % yield.

5 Example 34:

Unsaturated ketoacid 138 was obtained from ester 133 in 73 % overall yield after three consecutive steps, including saponification ( $\text{LiOH} / \text{H}_2\text{O} / \text{MeOH} / \text{THF}$ ), desilylation ( $\text{TBAF} / \text{THF}$ ), and oxidation of benzylic alcohol 137 using Dess-Martin periodinane. Anilide 139 was obtained by BOP-mediated condensation of compound 138 with  $\alpha\text{-phenylenediamine}$  in 83 % yield.

10

5        Regioselective hydrogenation of the acrylate moiety in **133** was  
accomplished by treatment with  $\text{NaBH}_4$  in the presence of  $\text{NiCl}_2$ , to afford the  
propionate **140** in high yield. Ketoacid **142** was then obtained in 31 % overall  
yield from **140** by an identical procedure to that followed in the synthesis of **138**  
from **133**. With compound **142** in hand, anilide **144** was obtained as described  
10      above (BOP / *o*-phenylenediamine). The low yield was due to a difficult  
purification process. To avoid oxime formation, hydroxamic acid **143** was  
synthesized from **142** in 73% overall yield over two steps, including BOP-  
mediated coupling with *N,O*-bistrimethylsilylhydroxylamine, followed by  
cleavage of silylated groups under acidic conditions (citric acid / MeOH).

**General procedure for synthesis of urea compounds**

15 To a solution of isocyanate (1.5 mmol) in 15 mL of anhydrous dichloromethane, was added a solution of 4-anilinylmethylacrylate (1.5 mmol) in dichloromethane (10 mL). The mixture was stirred at room temperature for 15 hours. After addition of ammonium chloride solution the new mixture was extracted from dichloromethane. The organic layers were combined and washed with ammonium chloride solution, water, brine and dried over magnesium sulfate. The crude was then flashed over silica gel using  $\text{CH}_2\text{Cl}_2 : \text{MeOH}$  (9.5:0.5) as eluent.

**Example 40:**

**Inhibition of Histone Deacetylase Enzymatic Activity**

15     HDAC inhibitors were screened against histone deacetylase enzyme in nuclear extracts prepared from the human small cell lung cancer cell line H446 (ATTC HTB-171) and against a cloned recombinant human HDAC-1 enzyme expressed and purified from a Baculovirus insect cell expression system.

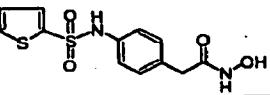

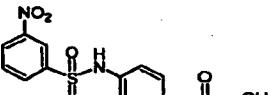

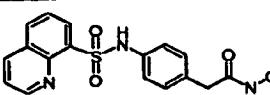

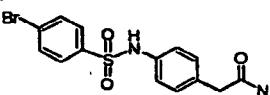

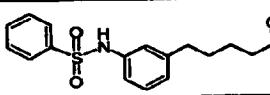

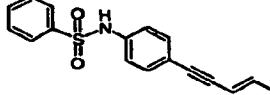

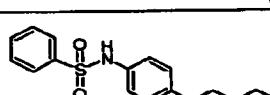

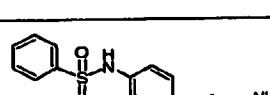

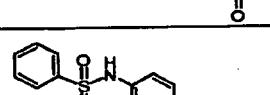

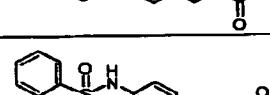

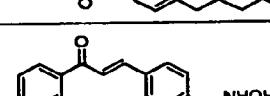

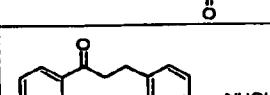

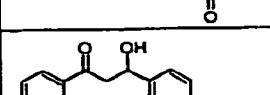

20     For deacetylase assays, 20,000 cpm of the [<sup>3</sup>H]-metabolically labeled acetylated histone substrate (M. Yoshida *et al.*, *J. Biol. Chem.* 265(28): 17174-17179 (1990)) was incubated with 30 µg of H446 nuclear extract or an equivalent amount of the cloned recombinant hHDAC-1 for 10 minutes at 37 °C. The reaction was stopped by adding acetic acid (0.04 M, final concentration) and HCl (250 mM, final concentration). The mixture was extracted with ethyl acetate and the released [<sup>3</sup>H]-acetic acid was quantified by scintillation counting. For inhibition studies, the enzyme was preincubated with compounds at 4 °C for 30 minutes prior to initiation of the enzymatic assay. IC<sub>50</sub> values for HDAC enzyme inhibitors were determined by performing dose response curves with individual compounds and determining the concentration of inhibitor producing fifty percent of the maximal inhibition.

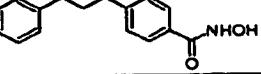

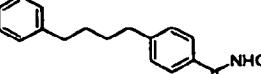

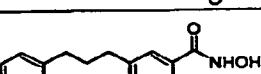

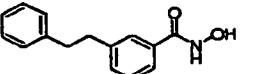

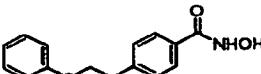

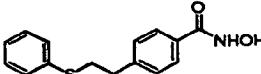

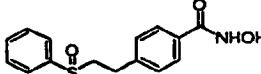

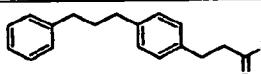

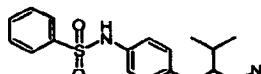

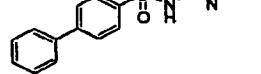

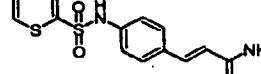

25     Representative data are presented in Table 4. In the first column are reported IC<sub>50</sub> values determined against histone deacetylase in nuclear extracts from H446 cells (pooled HDACs). In the second column are reported IC<sub>50</sub> values determined against recombinant human HDAC-1 enzyme (rHDAC-1). For less

5 active compounds, the data are expressed as the percent inhibition at the specified concentration.

**Inhibition of Histone Deacetylase in Whole Cells**

**1. Histone H4 acetylation in whole cells by immunoblots**

10 T24 human bladder cancer cells growing in culture were incubated with HDAC inhibitors for 16 hours. Histones were extracted from the cells after the culture period as described by M. Yoshida *et al.* (*J. Biol. Chem.* 265(28): 17174-17179 (1990)). 20 μg of total histone protein was loaded onto SDS/PAGE and transferred to nitrocellulose membranes. Membranes were probed with 15 polyclonal antibodies specific for acetylated histone H-4 (Upstate Biotech Inc.), followed by horse radish peroxidase conjugated secondary antibodies (Sigma).

5 Enhanced Chemiluminescence (ECL) (Amersham) detection was performed using Kodak films (Eastman Kodak). Acetylated H-4 signal was quantified by densitometry.

Data for selected compounds are presented in Table 5. Data are presented as the concentration effective for reducing the acetylated H-4 signal by 50%

5 2. Acid Urea Triton (AUT) gel analysis of histone acetylation.

Human cancer cells (T24, 293T or Jurkat cells) growing in culture are incubated with HDAC inhibitors for 24 h. Histones are extracted from the cells as described by M. Yoshida *et al.* (*J. Biol. Chem.* 265(28): 17174-17179 (1990)). Acid urea triton (AUT) gel electrophoresis is used for detection of acetylated histone molecules. Histones (150 µg of total protein) are electrophoresed at 80 V for 16 h at room temperature as described by M. Yoshida *et al.*, *supra*. Gels are stained with Coomassie brilliant blue to visualize histones, dried and scanned by densitometry to quantified acetylation of histones.

15 Example 42:**Antineoplastic Effect of Histone Deacetylase Inhibitors on Tumor Cells *In Vivo***

Eight to ten week old female BALB/c nude mice (Taconic Labs, Great Barrington, NY) are injected subcutaneously in the flank area with  $2 \times 10^6$  20 preconditioned A549 human lung carcinoma cells. Preconditioning of these cells is done by a minimum of three consecutive tumor transplantations in the same strain of nude mice. Subsequently, tumor fragments of approximately 30 mgs are excised and implanted subcutaneously in mice, in the left flank area, under Forene anesthesia (Abbott Labs, Geneve, Switzerland). When the tumors reach a 25 mean volume of 100 mm<sup>3</sup>, the mice are treated intravenously, subcutaneously, or intraperitoneally by daily injection, with a solution of the histone deacetylase inhibitor in an appropriate vehicle, such as PBS, DMSO/water, or Tween 80/water, at a starting dose of 10 mg/kg. The optimal dose of the HDAC inhibitor is established by dose response experiments according to standard 30 protocols. Tumor volume is calculated every second day post infusion according to standard methods (*e.g.*, Meyer *et al.*, *Int. J. Cancer* 43: 851-856 (1989)). Treatment with the HDAC inhibitors according to the invention causes a significant reduction in tumor weight and volume relative to controls treated with saline only (*i.e.*, no HDAC inhibitor). In addition, the activity of histone

5 deacetylase when measured is expected to be significantly reduced relative to saline treated controls.

**Example 43:**

10 **Synergistic Antineoplastic Effect of Histone Deacetylase Inhibitors and Histone Deacetylase Antisense Oligonucleotides on Tumor Cells *In Vivo***

The purpose of this example is to illustrate the ability of the histone deacetylase inhibitor of the invention and a histone deacetylase antisense oligonucleotide to synergistically inhibit tumor growth in a mammal. Preferably, the antisense oligonucleotide and the HDAC inhibitor inhibit the expression and activity of the same histone deacetylase.

15 As described in Example 10, mice bearing implanted A549 tumors (mean volume 100 mm<sup>3</sup>) are treated daily with saline preparations containing from about 0.1 mg to about 30 mg per kg body weight of histone deacetylase antisense oligonucleotide. A second group of mice is treated daily with pharmaceutically acceptable preparations containing from about 0.01 mg to about 5 mg per kg body weight of HDAC inhibitor.

20 Some mice receive both the antisense oligonucleotide and the HDAC inhibitor. Of these mice, one group may receive the antisense oligonucleotide and the HDAC inhibitor simultaneously intravenously via the tail vein. Another group may receive the antisense oligonucleotide via the tail vein, and the HDAC inhibitor subcutaneously. Yet another group may receive both the antisense oligonucleotide and the HDAC inhibitor subcutaneously. Control groups of mice are similarly established which receive no treatment (e.g., saline only), a mismatch antisense oligonucleotide only, a control compound that does not 25 inhibit histone deacetylase activity, and a mismatch antisense oligonucleotide with a control compound.

30 Tumor volume is measured with calipers. Treatment with the antisense oligonucleotide plus the histone deacetylase protein inhibitor according to the

5 invention causes a significant reduction in tumor weight and volume relative to controls.

## INTERNATIONAL SEARCH REPORT

International application No.  
PCT/IB 00/01881

### Box I Observations where certain claims were found unsearchable (Continuation of Item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1.  Claims Nos.: because they relate to subject matter not required to be searched by this Authority, namely:
  
2.  Claims Nos.: because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:  
see FURTHER INFORMATION sheet PCT/ISA/210
  
3.  Claims Nos.: because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

### Box II Observations where unity of invention is lacking (Continuation of Item 2 of first sheet)

This International Searching Authority found multiple inventions in this International application, as follows:

1.  As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.
  
2.  As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
  
3.  As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:
  
4.  No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

#### Remark on Protest

The additional search fees were accompanied by the applicant's protest.  
 No protest accompanied the payment of additional search fees.

**INTERNATIONAL SEARCH REPORT**

International Application No. PCT/IB 00 A1881

**FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210****Continuation of Box I.2**

The initial phase of the search revealed a very large number of documents relevant to the issue of novelty. So many documents were retrieved that it is impossible to determine which parts of the claim(s) may be said to define subject-matter for which protection might legitimately be sought (Article 6 PCT). For these reasons, a meaningful search over the whole breadth of the claim(s) is impossible. Consequently, the search has been restricted to compounds of claims 1, 11 and 26 with the Z=OM, 2-anilinyl, and 1, 3,4-thiadiazolyl. Claim 34 has been searched completely. However, still too many documents were retrieved, which are relevant to the question of novelty, which could not possibly all be cited. Therefore neither the search nor the search report may be considered complete. The cited documents are merely an arbitrary selection. However, all documents for compounds of the aforementioned restricted search related to the desired activity have been cited.

The applicant's attention is drawn to the fact that claims, or parts of claims, relating to inventions in respect of which no international search report has been established need not be the subject of an international preliminary examination (Rule 66.1(e) PCT). The applicant is advised that the EPO policy when acting as an International Preliminary Examining Authority is normally not to carry out a preliminary examination on matter which has not been searched. This is the case irrespective of whether or not the claims are amended following receipt of the search report or during any Chapter II procedure.
